Abstract

Introduction: Rapid maxillary expansion (RME) for the treatment of maxillary deficiency and posterior crossbite may induce changes in the vertical dimension. Expanders with occlusal splints have been developed to minimize unwanted vertical effects. Objective: This preliminary study used cephalometric radiographs to evaluate the vertical effects of RME using a Hyrax appliance in children with maxillary deficiency. Method: Twenty-six patients (11 boys; mean age = 8 years and 5 months) with maxillary deficiency and posterior crossbite were treated using a Hyrax appliance with an acrylic occlusal splint. Radiographs and cephalometric studies were performed before the beginning of the treatment (T1) and after RME active time (T2), at a mean interval of 7 months. Results were compared with normative values. Results and Conclusions: At the end of treatment, there were no statistically significant changes, and measurements were similar to the normative values. Data showed that there were no significant effects on vertical growth, which suggests that appliances with occlusal splints may be used to correct transverse deficiencies regardless of the patient’s growth pattern.

Keywords: Palatal expansion techniques. Vertical dimension. Interceptive orthodontics.

INTRODUCTION

Rapid maxillary expansion (RME) has been used to correct cases of maxillary deficiency and posterior crossbite in growing patients. The incidence of this type of malocclusion among children ranges from 7 to 23%, and RME has become a usual procedure in orthodontics.

Conventional RME results in midpalatal suture opening, increase of basal bone width and dental arch perimeter, and decrease of airflow resistance. However, treatment of transverse maxillary deficiencies using palatal expanders may have unwanted effects on the sagittal and vertical planes.

Studies that evaluated radiographs and dental casts found that the maxilla moves forward and downward, the maxillary molars extrude, and the mandibular plane angle and, consequently, the total facial height increases. However, other studies demonstrated that, although there were no statistical differences regarding the forward movement of the maxilla, the mandible and the palatal plane rotated clockwise. A systematic review of the long-term effects of RME concluded that there were no significant anteroposterior or vertical changes in the maxilla or mandible.

Several methods have been developed for RME, such as the bonded Hyrax developed by McNamara and Brudon (a Hyrax with an acrylic splint bonded to the occlusal surface of posterior teeth) to minimize the vertical effects of conventional expansion appliances.

The comparison of banded and bonded expanders revealed less forward and downward movement of the maxilla when the bonded appliance was used, which suggests that it should be used to minimize the unwanted vertical effects of RME. According to Garib et al, the side effects of RME with no vertical control are not significant in the long term, which do not contraindicate this treatment for patients with vertical growth pattern.

Despite the several studies in this area, there is still a controversy if bonded expanders provide vertical control. The aim of this preliminary study was to evaluate the cephalometric vertical effects of RME with a bonded Hyrax in children with transverse maxillary deficiency. Results were compared with normative follow-up values of dentofacial growth and development in untreated children.

MATERIAL AND METHODS

Sample selection

Twenty-six children (11 boys), with mean age of 8 years and 5 months (range = 6 years and 11 months to 10 years and 11 months) were included in this study. They all sought treatment in the Department of Orthodontics of the Ribeirão Preto Dental School, São Paulo University (FORP-USP). The inclusion criteria were good general and oral health, no caries or periodontal disease, erupted permanent maxillary and mandibular first molars, transverse maxillary deficiency and uni- or bilateral posterior crossbite. This study was approved by the Ethics Committee of the São Paulo University.

Occlusal radiographs were obtained to confirm the opening of the palatal suture after expansion, and lateral cephalograms were obtained before and after treatment for the analysis of vertical effects.

Modified Hyrax appliance

A bonded Hyrax (a rapid palatal expander with an acrylic occlusal splint) was used for RME, similar to the one described by McNamara and Brudon. The appliance was adjusted to the patient’s mouth to obtain the highest possible number of occlusal contact points.

The enamel was etched with 37% phosphoric acid gel (Unitek/3M, St. Paul, MN, USA) on the buccal and lingual surfaces of the posterior teeth. After that, a primer (Single Bond, Unitek/3M, St. Paul, MN, USA) was used and light cured for
15 seconds. A dual-cure resin cement (Rely X, Unitek/3M, St. Paul, MN, USA) was then applied on the internal surface of the acrylic splint and immediately placed in the patient’s mouth. After removing the excess, the resin was light-cured for 40 seconds, as recommended by the manufacturer.

Patients and parents received hygiene and appliance activation instructions (2 turns per day). The expansion phase was weekly monitored up to the point of crossbite overcorrection. The opening of midpalatal suture was confirmed through occlusal radiographs. The appliance was then fixed using acrylic resin and remained as a retainer for 107 days.

Cephalometric analysis
The cephalograms were obtained and scanned by only one technician in the Laboratory of Dental Radiographic Analysis and Control (LACIRO) of FORP-USP at two time points: before treatment (T1) and immediately after the removal of the expansion appliance (T2). The mean time interval between T1 to T2 was 7 months. All cephalograms were traced by the same examiner. Based on conventional cephalometric analysis (Steiner, Downs, Tweed, Ricketts, USP, Unicamp,) available in Radiocdef software (Radio Memory, Belo Horizonte/BH, Brazil), we developed our own analytical method using 9 angles and 3 linear measurements (Fig 2) to evaluate the vertical bone changes and the facial height after the treatment.

Statistical analysis
To evaluate the error of method, 12 cephalograms were traced twice by the same examiner at an interval of at least 3 hours. The Pearson (r) correlation test and a t-test for r were used to statistically compare the values. Results were described and compared as means and standard deviations using a paired t-test. Statistical significance was tested at $p \leq 0.05$. To define whether treatment affected the vertical dimension in our experimental group, the values obtained for this sample were compared to a group of untreated patients.$^7,24$

**FIGURE 1** - Bonded Hyrax expander with acrylic occlusal splint used in this study.

**FIGURE 2** - Cephalogram showing the landmarks, lines, planes and cephalometric measurements used in this study.
RESULTS

There was a high correlation ($r \geq 0.99$) between repeated measurements to evaluate the error of method, with a great significance for $r$ ($p<0.001$).

Comparison of angular and linear cephalometric measurements in the vertical plane between T1 and T2 revealed that the changes were not statistically significant (Table 1), and that there was no change in vertical growth pattern. Although there was no significance, the greatest variation was found in the anterior facial height (AFH), with the mean difference between T1 and T2 of 0.5958 mm.

According to the Bolton’s7 dentofacial growth and development standards, FMA and SN-GoGn values for children of 8 years of age are 26.2º and 31.6º, respectively, with a small reduction of these angles every year. The mandibular plane angle (FMA) established by Ricketts24 is about 28º at 3 years of age, with a 1º reduction every 3 years up to maturity. Therefore, at 8 years of age (a compatible phase with the mean initial age of this sample), FMA should be about 26º. The mean FMA angle in our sample was 26º at T1 and 26.2º at T2. Although there was an increase in the mean value of SN-GoGn angle when compared to the Bolton standards (37.06º at T1 and 36.80º at T2), there were no significant changes in this angle. Taken all together, the data suggested that there were no changes in the vertical growth of the mandible.

Moreover, the linear values used in this sample (AFH, UpAFH and LoAFH) were greater than the Bolton’s7 standards. However, they were balanced between them, with a small but not statistically significant increase between T1 and T2, which is in agreement with the variations described by that author.

DISCUSSION

Different expanders with occlusal splints have been proposed\textsuperscript{19,21,28} to avoid changes in the vertical dimension when using banded appliances\textsuperscript{10,11,14,16,17,27,29} and the unfavorable effect on patient’s facial height.\textsuperscript{3,11,19,25} The appliance described by McNamara and Brudon\textsuperscript{19} was chosen for this study because it is widely used in orthodontics, it is easy to manufacture and it is more hygienic.

The cephalometric measurements used in this study evaluated the vertical growth pattern of the patients. The focus was in the anterior facial height, and maxillary and occlusal plane tipping, relatively to the cranial base and the mandible, respectively. There was no control group in this study, and some of the results were compared with normative follow-up values for growth without orthodontic treatment.

The lack of statistical significance in the vertical measurements between T1 and T2 demonstrated the maintaining of the vertical pattern in the evaluated group. These results are in agreement with those reported by previous studies,\textsuperscript{3,19,23,25} which did not find any side effects on the vertical plane when bonded expanders were used, one of the great advantages of this type of treatment. These findings might be associated with the fact that appliances with an acrylic occlusal splint may prevent alveolar growth, excessive eruption of anchorage teeth, tilting of the alveolar processes and, consequently, buccal movement of maxillary posterior teeth.\textsuperscript{3,19,21,25,28} In contrast, clockwise mandibular rotation in response to RME was seen in other studies\textsuperscript{3,8} using banded and bonded appliances. In both cases, the explanation was in the buccal movement of the anchorage teeth. Such mandibular rotation was not confirmed in this study, and may be assigned to the skeletal resistance between the maxillary segments that did not allow a symmetrical expansion of the maxilla.\textsuperscript{3,8}

It can be suggested that the decrease of the palatal plane angle in relation to the cranial base (SN-PP) might be resulted from the downward displacement of the posterior region of the maxilla\textsuperscript{3,10,25} rather than from the upward displacement of the anterior region. The downward and forward maxillary movement after RME, also reported by Haas,\textsuperscript{16} resulted from the fact that this procedure is traumatic and causes fractures along the maxillary tuberosity, which facilitated such movements.\textsuperscript{20}

Although several studies found statistically and clinically significant short-term changes in the vertical dimension of patients with banded expansion appliances,\textsuperscript{10,11,14,16,17,27,29} we believe that these changes are not significant in the long run, and the procedure should not be contraindicated for patients with a vertical growth pattern.\textsuperscript{14}

The results of this study suggested that vertical changes after RME with occlusal splint also have no statistical and clinical significance. As the means found in this study were similar to normative values,\textsuperscript{7,24} we believe that the bonded Hyrax might be a good option for the correction of transverse maxillary deficiency, regardless of vertical dimension or facial pattern.

This is a preliminary study of the vertical effects of palatal expansion using an expander with occlusal splints. As it is a longitudinal study, other patients, as well as a control group, are still being followed up. This sample selection was based only on maxillary transverse dimension and did not take into consideration aspects associated with growth pattern. Further studies with a standardized sample should be conducted to clarify the benefits of expansion appliances with occlusal splints for patients with a vertical growth pattern.

CONCLUSIONS

The results of this study and their comparison with normative dentofacial growth and development values revealed that the
changes in the vertical plane are not statistically significant, which suggests that the vertical growth of patients that undergo this type of treatment does not change due to the use of bonded Hyrax. Therefore, this type of appliance may be an alternative for the correction of posterior crossbite in individuals with a vertical growth pattern.
