(Received 21 December 2011; published 13 March 2012)

We extend our earlier results delineating the supersymmetry reach of the CERN Large Hadron Collider operating at a center-of-mass energy $\sqrt{s} = 7$ TeV to integrated luminosities in the range 5–30 fb$^{-1}$. Our results are presented within the paradigm minimal supergravity model or constrained minimal supersymmetric standard model. Using a six-dimensional grid of cuts for the optimization of signal to background ratio—including missing $E_T$—we find for $m_\tilde{g} \sim m_\tilde{q}$ an LHC $5\sigma$ supersymmetry discovery reach of $m_\tilde{q} \sim 1.3$, 1.4, 1.5, and 1.6 TeV for 5, 10, 20, and 30 fb$^{-1}$, respectively. For $m_\tilde{g} \gg m_\tilde{q}$, the corresponding reach is instead $m_\tilde{g} \sim 0.8$, 0.9, 1.0, and 1.05 TeV, for the same integrated luminosities.

I. INTRODUCTION

In 2011, the CERN Large Hadron Collider produced proton-proton collisions at a center-of-mass energy $\sqrt{s} = 7$ TeV (LHC7) and enabled both ATLAS and CMS experiments to each accumulate over 5 fb$^{-1}$ of useful data. The current plan is to resume running with $pp$ collisions in early 2012, with a goal to amass in the vicinity of 10–30 fb$^{-1}$ of usable data. The 2012 run will likely be followed by a shut down for ~2.5 years so that various upgrades may be implemented; a turn-on at or near design energy of $\sqrt{s} = 14$ TeV is then expected around 2015.

While many LHC analyses are focused on the elusive Higgs boson, the search for weak scale supersymmetry (SUSY) [1] remains an important part of the LHC program. In a previous paper [2], we presented projections for the LHC7 $5\sigma$ discovery reach for SUSY in the paradigm minimal supergravity (mSUGRA) or constrained minimal supersymmetric standard model (CMSSM) model [3]. In that study, we presented discovery strategies for early SUSY discovery and made projections for the LHC7 reach for a variety of integrated luminosities ranging from 100 fb$^{-1}$ up to 2 fb$^{-1}$, well beyond what was then expected to be delivered in the entire 7 TeV run. LHC reach projections for $\sqrt{s} = 14$ TeV (LHC14) have been reported in earlier studies [4].

Recent analyses (performed within the mSUGRA model) of the LHC7 data by the ATLAS [5] and CMS [6] experiments based on just ~1 fb$^{-1}$ of integrated luminosity have found no indication of SUSY so far, yielding 95% C.L. lower limits of $m_\tilde{q} \sim m_\tilde{g} \gtrsim 1$ TeV for comparable gluino and squark masses, and $m_\tilde{g} \gtrsim 0.6$ TeV for the case where $m_\tilde{q} \gg m_\tilde{g}$. It is worth emphasizing that although all squarks are by assumption degenerate within the mSUGRA framework, the squark mass limit cited above arises mostly from signals for first-generation squarks that are much more copiously produced from $qq$ and $gq$ initial states than their second- and third-generation cousins. In other words, the LHC7 squark limit really applies to up- and down-type squarks—other squark flavors may be significantly lighter than the quoted bounds. These LHC7 bounds do not apply to third-generation squarks or to electroweak-inos, the only particles with significant couplings to the Higgs sector and to which the naturalness arguments that yield upper-mass bounds on sparticles apply. Indeed, models with $O(10–100)$ TeV gluinos and first-generation sfermions but with sub-TeV third-generation sfermions and electroweak-inos [7] that have been proposed to ameliorate the SUSY flavor and $CP$ problems are not in conflict with these LHC7 data.

The LHC has performed spectacularly and has already delivered an integrated luminosity of 5 fb$^{-1}$ and, as we mentioned, is expected to deliver a comparable or larger data set in 2012. This motivated us to extend our earlier projections [2] of the LHC7 reach for SUSY to integrated luminosities up to 30 fb$^{-1}$. As before, we work within the mSUGRA framework, the parameter space of which is given by

$$m_0, \quad m_{1/2}, \quad A_0, \quad \tan\beta, \quad \text{sign}(\mu).$$

(1.1)

Here, $m_0$ is a common grand unified theory (GUT)-scale soft SUSY-breaking (SSB) scalar mass; $m_{1/2}$ is a common GUT-scale SSB gaugino mass; $A_0$ is a common GUT-scale trilinear SSB term; $\tan\beta$ is the ratio of the Higgs field vacuum expectation value, and $\mu$ is the superpotential Higgsino mass term whose magnitude but not sign is constrained by the electroweak symmetry-breaking minimization conditions.

The event generator used, total cross sections, and number of renormalization scale is chosen to match the NLO cross section. For the final states containing multiple jets, which given a mSUGRA parameter set, generates all and PYTHIA [10] for the subsequent showering and hadronization. The hadronic calorimetry energy resolution is taken to be 80%/$\sqrt{E}$ + 3% for $|\eta| < 2.6$ and forward calorimeter is 100%/$\sqrt{E}$ + 5% for $|\eta| > 2.6$, where $\otimes$ denotes a combination in quadrature. The electromagnetic calorimeter energy resolution is assumed to be 3%/$\sqrt{E}$ + 0.5%. We used the cone-type ISAJET [12] jet-finding algorithm to group the hadronic final states into jets. Jets and isolated lepton are defined as follows:

(i) Jets are hadronic clusters with $|\eta| < 3.0$, $R = \sqrt{\Delta\eta^2 + \Delta\phi^2} \leq 0.4$, and $E_T(\text{jet}) > 50$ GeV.

(ii) Electrons and muons are considered isolated if they have $|\eta| < 2.0$, $p_T(l) > 10$ GeV with visible activity within a cone of $\Delta R < 0.2$ about the lepton direction, $\Sigma E_T^{\text{vis}} < 5$ GeV.

(iii) We identify hadronic clusters as $b$ jets if they contain a $B$ hadron with $E_T(B) > 15$ GeV, $\eta(B) < 3$, and $\Delta R(B, \text{jet}) < 0.5$. We assume a tagging efficiency of 60%, and light quark and gluon jets can be mistagged as a $b$ jet with a probability 1/150 for $E_T \leq 100$ GeV and 1/50 for $E_T \geq 250$ GeV, with a linear interpolation for 100 GeV $\leq E_T \leq 250$ GeV [15].

As in Ref. [2], we define the signal to be observable if

$$S \geq \max[5\sqrt{B}, 0.2B],$$

where $S$ and $B$ are the expected number of signal and background events, respectively, for an assumed value of integrated luminosity. The requirement $S \geq 0.2B$ is imposed to avoid the possibility that a small signal on top of a large background could otherwise be regarded as statistically significant, but whose viability would require the background level to be known with exquisite precision in order to establish a discovery. For cases with very low signal and background event numbers, we require the Poisson probability to correspond to the 5$\sigma$ level.

---

By $k$ factor, here, we actually mean $\sigma^{NLO}/\sigma^{LO}$. Normally, one compares the two cross sections using an identical renormalization/factorization scale for the two cases. Here, we merely compute $\sigma^{LO}$ using ALPGEN and $\sigma^{NLO}$ using MCFM, using the preprogrammed default scale choices for the latter.
The grid of cuts used in our optimized analysis is:

(i) $E_T^{\text{miss}} > 50, 100–1000 \text{ GeV}$ (in steps of 100 GeV);
(ii) $n(\text{jets}) \geq 2, 3, 4, 5, \text{ or } 6$;
(iii) $n(b\text{-jets}) \geq 0, 1, 2, \text{ or } 3$;
(iv) $E_T(j_1) > 50–300 \text{ GeV}$ (in steps of 50 GeV) and 400–1000 GeV (in steps of 100 GeV) [jets are ordered $j_1 - j_n$, from highest to lowest $E_T$];
(v) $E_T(j_2) > 50–200 \text{ GeV}$ (in steps of 30 GeV) and 300, 400, 500 GeV;
(vi) $n(\ell) = 0, 1, 2, 3, (\text{OS}), (\text{SS}), \text{and inclusive channel}$ $n(\ell) \geq 0$ [here, $\ell = e, \mu$];
(vii) $10 \text{ GeV} \leq m(\ell^+\ell^-) \leq 75 \text{ GeV}$ or $m(\ell^+\ell^-) \geq 105 \text{ GeV}$ [for the OS, same flavor dileptons only], and
(viii) transverse sphericity $S_T > 0.2$.

We show in Fig. 1 the optimized $5\sigma$ discovery reach of
LHC7 for various choices of integrated luminosity in the $m_0$ vs $m_{1/2}$ plane. We also take $A_0 = 0$, $\tan\beta = 45$, and $\mu > 0$, with $m_l = 172.6 \text{ GeV}$.

Glino iso-mass contours are shown as obtained using the ISASUGRA routines \[16\] in ISAJET. We see from Fig. 1 that with $\sim 1 \text{ fb}^{-1}$ of integrated luminosity, the LHC7 sensitivity does indeed extend to $m_{\tilde{g}} \sim 1.1 \text{ TeV}$ for $m_{\tilde{q}} \sim m_{\tilde{g}}$ and to $m_{\tilde{g}} \sim 0.65 \text{ TeV}$ for $m_{\tilde{q}} \gg m_{\tilde{g}}$.\[3\] For $5 \text{ fb}^{-1}$ of integrated luminosity [for which we expect ATLAS and CMS analyses in spring 2012], the LHC discovery reach extends to $m_{\tilde{g}} \sim 1.3 \text{ TeV}$ for $m_{\tilde{q}} \sim m_{\tilde{g}}$ and to $m_{\tilde{g}} \approx 0.8 \text{ TeV}$ for $m_{\tilde{q}} \gg m_{\tilde{g}}$. As integrated luminosity moves into the 20–30 fb$^{-1}$ regime, the LHC7 reach for $m_{\tilde{g}} \sim m_{\tilde{g}}$ moves up to $m_{\tilde{g}} \sim 1.5–1.6 \text{ TeV}$. For the case where $m_{\tilde{q}} \gg m_{\tilde{g}}$, the 20–30 fb$^{-1}$ LHC reach approaches $m_{\tilde{g}} \sim 1 \text{ TeV}$. We stress that—as discussed above—while nonobservation of the signal at LHC7 may qualitatively point toward very heavy gluinos and first-generation squarks, \textit{this does not} in and of itself preclude SUSY as the new physics that stabilizes the weak scale \[7\] because third-generation squarks and electroweak-inos could still be at the sub-TeV scale.

While our results are presented for the particular choice of mSUGRA parameters $A_0 = 0$ and $\tan\beta = 45$, we emphasize here that we expect these results to also hold for

\[2\]Recent evidence from ATLAS \[17\] and CMS \[18\] using $5 \text{ fb}^{-1}$ of data show some evidence for a Higgs scalar $h$ with $m_h \sim 125 \text{ GeV}$. For $A_0 = 0$, it is very difficult to accommodate such a Higgs mass in the mSUGRA model. For $A_0 \sim \pm 2 m_{\tilde{g}}$, then $m_h \sim 125 \text{ GeV}$ can be accommodated but mainly at rather high $m_0 \sim 2–10 \text{ TeV}$. For more details, see e.g. Ref. \[19\]. Our reach projections are largely insensitive to variation in $A_0$ (and subsequent small changes in $m_h$) as explained below.

\[3\]We stress that the curves presented here include an optimization over several search channels and correspond to a $5\sigma$ discovery reach. Care must be taken when comparing these results with experimental bounds, which are usually presented for single channels at 95% C.L. ($\sim 2\sigma$).
other choices of $A_0$ and $\tan \beta$ and also for $\mu < 0$. Variation of $A_0$ mainly affects third-generation sparticle masses, while the reach is determined mostly by $m_\tilde{g}$ and the first-generation squark masses. Moreover, variation of $\tan \beta$ mainly affects the size of $b$ and $\tau$ Yukawa couplings, and these feed only weakly into the reach plots: for instance, sparticle decays to third-generation matter are enhanced at large $\tan \beta$ [20] where $b$-tagging may somewhat enhance the LHC reach for gluinos [21], as already demonstrated by ATLAS [22].

To give the reader an idea of the dominant event topologies in which experiments at LHC7 will be able to probe SUSY in the 2012 run, we show in Fig. 2 the optimized $5\sigma$ reach via the $0\ell$, $1\ell$, OS dilepton, SS dilepton, and trilepton channels for $20 \text{ fb}^{-1}$. The striking feature of the figure is that while the reach is dominated by the low-multiplicity ($n_\ell = 0, 1$) lepton channels for $m_\tilde{q} \lesssim 1.5 \text{ TeV}$, the reach in the low-background but rate-limited trilepton channel becomes competitive with that in other channels if squarks are essentially decoupled at LHC7, as could well be the case. We have checked that this is also true for an integrated luminosity of $10 \text{ fb}^{-1}$.

In summary, we have presented updated $5\sigma$ discovery contours for the paradigm mSUGRA/CMSSM SUSY model for LHC7 with $5–30 \text{ fb}^{-1}$ of integrated luminosity. These results help us to understand the capabilities of LHC7 for discovering supersymmetry in 2012–2013. Within mSUGRA, for integrated luminosity $20–30 \text{ fb}^{-1}$, we expect LHC7 to probe $m_\tilde{g}$ up to $\sim 1.6 \text{ TeV}$ for $m_\tilde{q} \approx m_\tilde{g}$, while we expect LHC7 to probe up to $m_\tilde{g} \sim 1 \text{ TeV}$ for $m_\tilde{q} \gg m_\tilde{g}$. If squarks are much heavier than gluinos, the reach at LHC7 via the inclusive trilepton channel will be competitive in reach with the canonical jets plus $E_T^{\text{miss}}$ channel.
